# BLG453E COMPUTER VISION

## Fall 2018 Term

## Week 8

İstanbul Technical University
Computer Engineering Department

Instructor: Prof. Gözde ÜNAL

Teaching Assistant: Enes ALBAY

David Marr, a pioneer of "vision" in 70's: "*Vision is the process of discovering from images what is present in the world, and where it is*". Indeed, Vision is MUCH MORE THAN THAT!

## Learning Outcomes of the Course

Students will be able to:

1. Discuss the main problems of computer (artificial) vision, its uses and applications
2. Design and implement various image transforms: point-wise transforms, neighborhood operation-based spatial filters, and geometric transforms over images
3. Define and construct segmentation, feature extraction, and visual motion estimation algorithms to extract relevant information from images
4. Construct least squares solutions to problems in computer vision
5. Describe the idea behind dimensionality reduction and how it is used in data processing
6. Apply object and shape recognition approaches to problems in computer vision

## Week 7: Template Matching and Feature Extraction: Hough Method, Detection of Lines, circles etc, and Corner Detection

At the end of Week 7-8: Students will be able to:

3. Define and construct segmentation, feature extraction, and visual motion estimation algorithms to extract relevant information from images

## Image Feature Extraction: Why we need features?

**Example: Build a Panorama**

This panorama was generated using **AUTOSTITCH** (freeware), available at http://www.cs.ubc.ca/~mbrown/autostitch/autostitch.html

M. Brown and D. G. Lowe. Recognising Panoramas. ICCV 2003

45/59

## Image Feature Extraction: Why we need features?

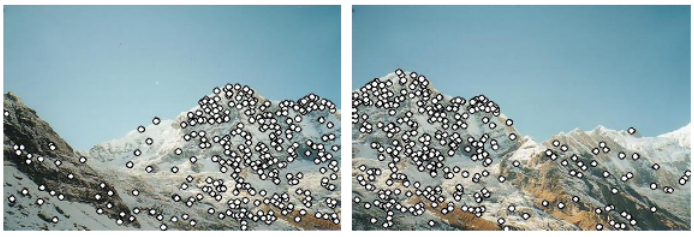
### How do we build panorama?

- We need to match (align) images

46/59

### Matching with Features

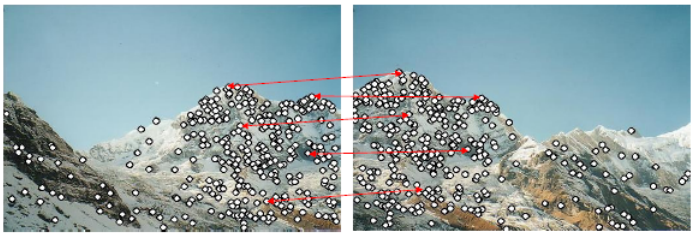
- Detect feature points in both images



47/59

## Matching with Features

- Detect feature points in both images
- Find corresponding pairs



48/59

## Matching with Features

- Detect feature points in both images
- Find corresponding pairs
- Use these pairs to align images

49/59

## More motivation…

- Feature points are used also for:
  - *Robot navigation*
  - *Object recognition*
  - *Image alignment (panoramas)*
  - *3D reconstruction*
  - *Motion tracking*
  - *Indexing and database retrieval*
  - *… other*

52/59

## Matching with Features

- Problem 1:
  - *Detect the* same *point* independently *in both images*

no chance to match!

We need a repeatable detector

50/59

## Matching with Features

- Problem 2:
  - *For each point correctly recognize the corresponding one*

We need a reliable and distinctive descriptor

51/59

## Most Popular Feature Detectors

Hough method for line and other parametric structure detection (1959, 1972)

Harris Corner Detector (1988)

SIFT Feature Detector (2004) (you are not responsible in this class, because time does not permit to study it thoroughly, but please study it on your own, as it was one of the most popular feature extractors of early 2000's.)

## Template Matching

- Simple filtering method of detecting a particular feature in the image
- Provided that the appearance of this feature in the image is known accurately, we can detect it with a TEMPLATE.
- Template: a subimage that looks like the image of the object

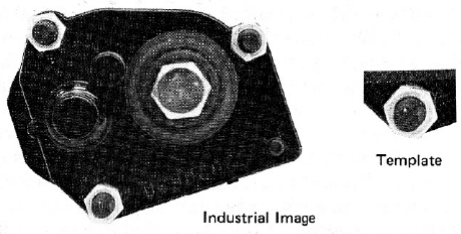


**Fig. 3.3** An industrial image and template for a hexagonal nut.

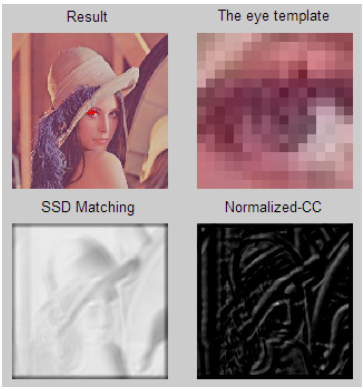
## Template Matching

- A similarity measure is computed to measure how well the template matches the image data for each possible template location
- Select the point of maximal match as possible template location



Fast/Robust Template Matching
by Dirk-Jan Kroon
Matlab central exchange

https://www.mathworks.com/matlabcentral/fileexchange/24925-fast-robust-template-matching

## Template Matching

• A widely used similarity measure between a function f and a template t:

Sum of Squared Differences (SSD):

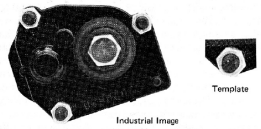


Fig. 3.3 An industrial image and template for a hexagonal nut.

$$d(\mathbf{y})^2 = \sum_{\mathbf{x}} \left[ f(\mathbf{x}) - t(\mathbf{x}-\mathbf{y}) \right]^2$$

• Here $\sum_{\mathbf{x}}$ means $\sum_{x=-M}^{M} \sum_{y=-N}^{N}$ , M and N: size of the template t

• If the image at point y is an exact match: $d(\mathbf{y}) \approx 0$

## Template Matching

• Expand the $d(\mathbf{y})^2$ expression

$$d(\mathbf{y})^2 = \sum_{\mathbf{x}} \left[ f^2(\mathbf{x}) - 2 f(\mathbf{x})\ t(\mathbf{x}-\mathbf{y}) + t^2(\mathbf{x}-\mathbf{y}) \right]$$

• $t^2$ is constant, and assuming $f^2$ is constant, what is left is

Cross Correlation between f and t:

$$CC_{ft}(\mathbf{y}) = \sum_{\mathbf{x}} f(\mathbf{x})\ t(\mathbf{x}-\mathbf{y})$$

Maximized when portion of image f under t is identical to t!

• Like convolution: Template-matching calculations are visualized as template being shifted across the image to different offsets, multiplied, and products are added

## Template Matching

Cross Correlation (CC): $$CC_{ft}(\mathbf{y}) = \sum_{\mathbf{x}} f(\mathbf{x})\ t(\mathbf{x}-\mathbf{y})$$

Note that this is the same as convolution of f(x) by t(-x)

→ template matching is a kind of Filtering for Object Detection

| *Template* | *Image* | *Correlation* |
|---|---|---|
| 1 1 1 | 1 1 0 0 0 | 7 4 2 x x |
| 1 1 1 | 1 1 1 0 0 | 5 3 2 x x |
| 1 1 1 | 1 0 1 0 0 | 2 1 9 x x |
| | 0 0 0 0 0 | x x x x x |
| | 0 0 0 0 8 | x x x x x |
| | | x = undefined |

**Fig. 3.4** (a) A simple template. (b) An image with noise. (c) The aperiodic correlation array of the template and image. Ideally peaks in the correlation indicate positions of good match. Here the correlation is only calculated for offsets that leave the template entirely within the image. The correct peak is the upper left one at 0, 0 offset. The "false alarm" at offset 2, 2 is caused by the bright "noise point" in the lower right of the image.

## Template Matching

e.g. A bright spot in the image can badly influence the correlation matching!

CC may work if the average image intensity f varies slowly compared to the template size

$$CC_{ft}(u,v) = \sum_{x,y} f(x,y)\ t(x-u,y-v)$$

Normalized Cross Correlation:

$$NCC_{ft}(u,v) = \frac{\sum_{x,y}\left[f(x,y)-\bar{f}\right]\left[t(x-u,y-v)-\bar{t}\right]}{\left\{\sum_{x,y}\left[f(x,y)-\bar{f}\right]^2 \sum_{x,y}\left[t(x-u,y-v)-\bar{t}\right]^2\right\}^{0.5}}$$

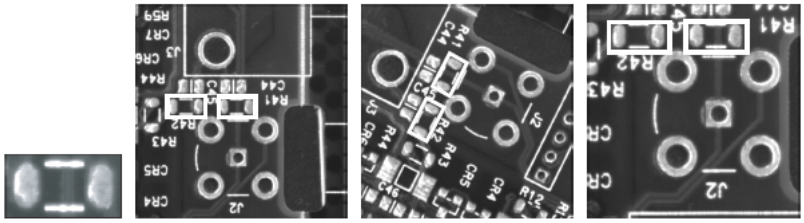
where the means are subtracted and divided by their standard deviations, NCC less dependent on the local properties of the template and the input image than CC

## Normalized Cross Correlation

NCC is typically used in template matching problems of computer vision

$$NCC_{ft}(u,v) = \frac{\sum_{x,y}\left[f(x,y)-\bar{f}\right]\left[t(x-u,y-v)-\bar{t}\right]}{\left\{\sum_{x,y}\left[f(x,y)-\bar{f}\right]^2 \sum_{x,y}\left[t(x-u,y-v)-\bar{t}\right]^2\right\}^{0.5}}$$

Could the form of NCC above help with matching the parts below?



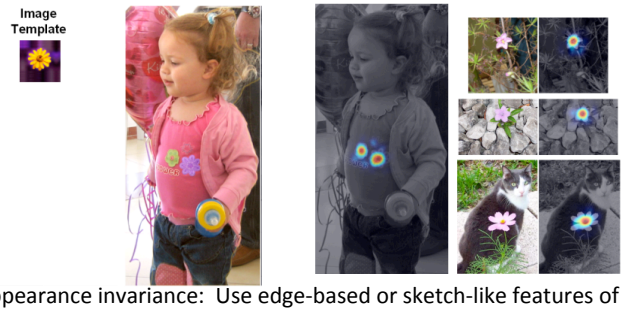
A B C D

When the pattern is rotated, scaled, or is imaged in a different lighting condition?

Different rotations and scales should be taken into account

Figure from National Instruments website: what to expect from a pattern matching tool?

## Advanced Methods



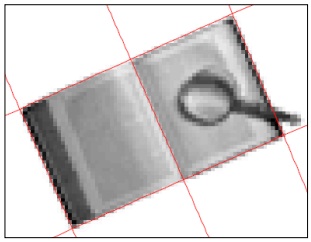
For illumination and appearance invariance: Use edge-based or sketch-like features of the object that is searched for

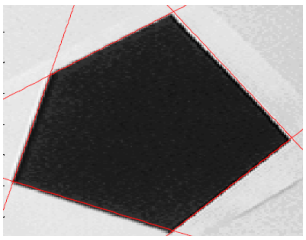
http://www.wisdom.weizmann.ac.il/~vision/SelfSimilarities.html

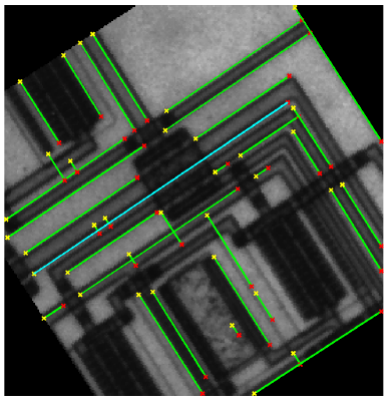
Next: Feature Extraction from images

- Lines
- Quadratic forms
- Corners
- ...

## Line Detection and Parameterization: Hough Transform







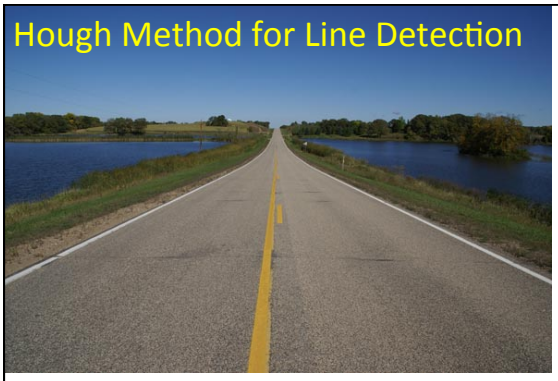
## Hough Method for Line Detection

Goal: Detecting Straight Lines in Images

Assume we have detected some points likely to be on lines in an image

Hough technique will organize these points into straight lines by considering all possible straight lines at once and rating each on how well it explains the data

## Hough Method for Line Detection



## Hough Method for Line Detection

Equation for a line: $y = mx + c$

Q:What are the lines that could pass through point (x',y') below?
A: All the lines that satisfy $y' = mx' + c$

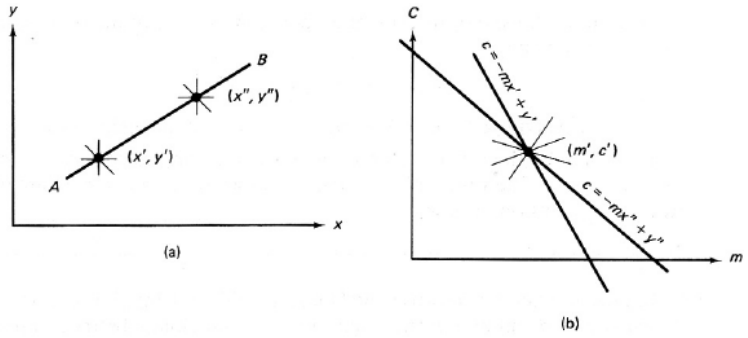


**Fig. 4.5** A line (a) in image space; (b) in parameter space.

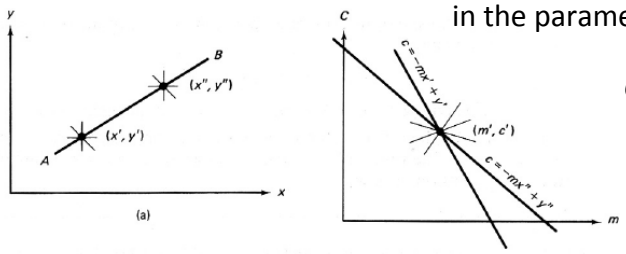
## Hough Method for Line Detection



• Fixing (x',y'), the line equation is now in the parameter space (m,c):

$$c = -mx + y$$

• A second point (x'',y'') will also have a line in the parameter space

→ All such lines will intersect at (m',c') → this point in the parameter space corresponds to the line AB in the image space with coord (x,y)

## Hough Method for Line Detection

**Algorithm 4.1:** Line Detection with the Hough Algorithm

1. Quantize parameter space between appropriate maximum and minimum values for $c$ and $m$.
2. Form an accumulator array $A(c, m)$ whose elements are initially zero.
3. For each point (x,y) in a *gradient* image such that the strength of the gradient exceeds some threshold, increment all points in the accumulator array along the appropriate line, i.e.,

$$A(c, m) := A(c, m) + 1$$

for $m$ and $c$ satisfying $c = -mx + y$ within the limits of the digitization.

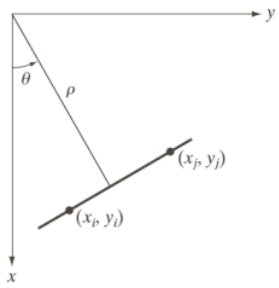
4. Local maxima in the accumulator array now correspond to collinear points in the image array. The values of the accumulator array provide a measure of the number of points on the line.

Q: Do you see where we might run into problem with this algorithm?

## Hough Method for Line Detection

In the previous algorithm, when there is a vertical line in the image, m: the slope of the line is $\infty$

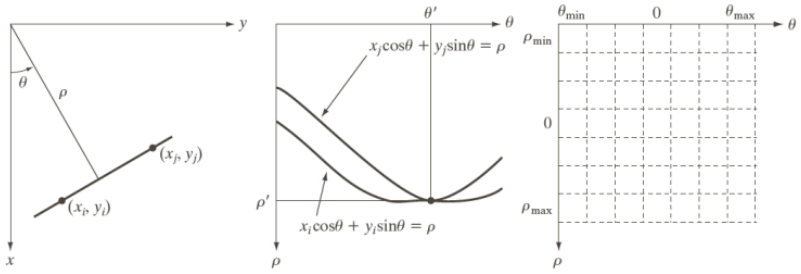
Recommended Rather than (c,m) parameters, use the line polar parameterization with : $(\rho,\theta)$



$$x\cos\theta + y\sin\theta = \rho$$

Same idea as before, but with different parameterization of the line: now the lines become sinusoidal curves in the parameter space →

## Hough Method for Line Detection



a b c

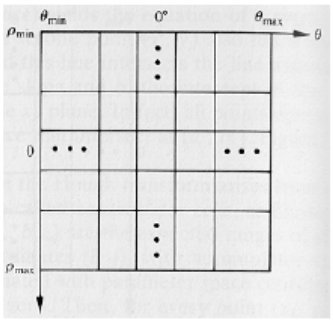
**FIGURE 10.32** (a) $(\rho, \theta)$ parameterization of line in the $xy$-plane. (b) Sinusoidal curves in the $\rho\theta$-plane; the point of intersection $(\rho', \theta')$ corresponds to the line passing through points $(x_i, y_i)$ and $(x_j, y_j)$ in the $xy$-plane. (c) Division of the $\rho\theta$-plane into accumulator cells.

The lines with the parameterization: $x\cos\theta + y\sin\theta = \rho$

become sinusoidal curves in the parameter space

## Hough Algorithm

1. Quantize the parameter space
   $P[\rho_{min}, \ldots, \rho_{max}][\theta_{min}, \ldots, \theta_{max}]$ (accumulator array)



2. For each edge point $(x, y)$

   For($\theta = \theta_{min}$; $\theta \le \theta_{max}$; $\theta$++) {

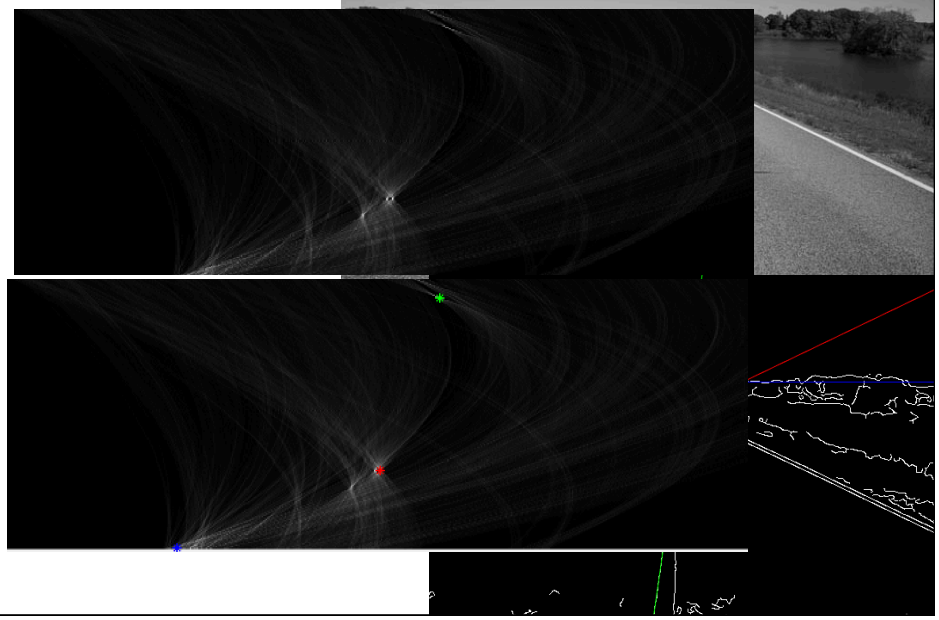
   $\rho = x\cos\theta + y\sin\theta$; /* round off if needed *

   ($P[\rho][\theta]$)++; /* voting */

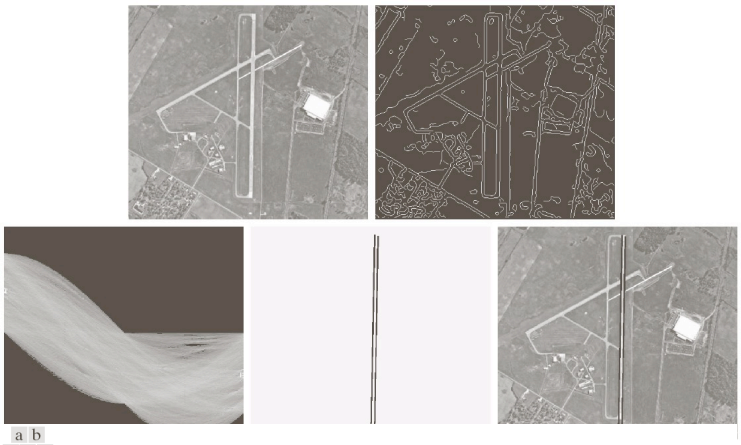
   }

3. Find local maxima in $P[\rho][\theta]$

## Line Detection: Hough Transform



## Line Detection: Hough Transform



a b
c d e

**FIGURE 10.34** (a) A 502 × 564 aerial image of an airport. (b) Edge image obtained using Canny's algorithm. (c) Hough parameter space (the boxes highlight the points associated with long vertical lines). (d) Lines in the image plane corresponding to the points highlighted by the boxes). (e) Lines superimposed on the original image.

Digital Filtering of Images, Gonzalez and Woods Book

## General Hough Method

- Can be extended to other functions

where a is a parameter vector:

$$f(\mathbf{x},\mathbf{a}) = 0$$

For example, Circle :

$$(x-a)^2 + (y-b)^2 = r^2$$

$$f(\mathbf{x},\mathbf{a}) = (x-a)^2 + (y-b)^2 - r^2$$

$$\mathbf{x} = (x,y) \qquad \mathbf{a} = (a,b,r)$$

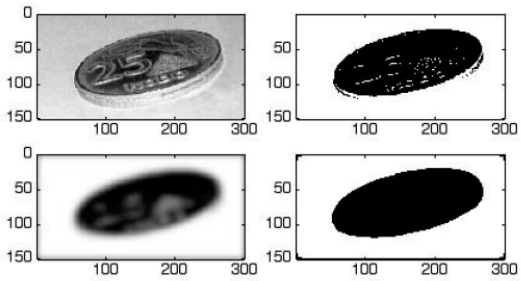
known feature coordinates, e.g. Edge point coordinates

Parameter vector to be estimated

## General Hough Method

Try to obtain these yourself

## Ellipse Detection



General Ellipse equation (including rotation) is a quadratic form:

$$ax^2 + bxy + cy^2 + dx + ey + f = 0$$

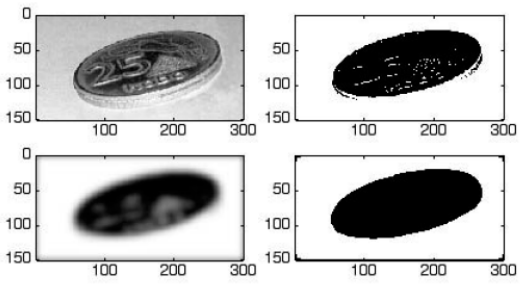
We can use the LEAST SQUARES technique, to solve for the parameters of the ellipse.

Recall: Ellipse not centered but with no rotation: $((x - x0)/a)^2 + ((y - y0)/b)^2 = 1$

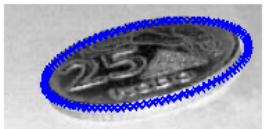
## Ellipse Detection

ON BOARD: Construct the LEAST SQUARES problem using this equation, and solve for the parameters of the ellipse

E.g. Take your ellipse equation: $ax^2 + bxy + cy^2 + dx + ey = 1$



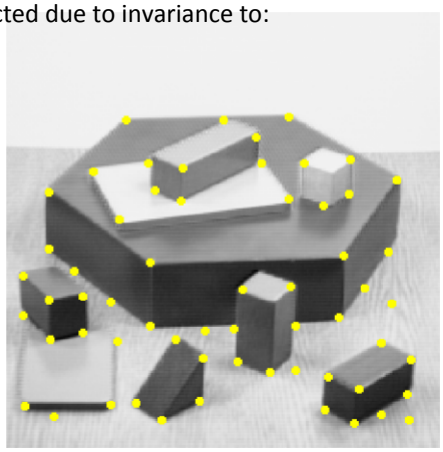
Overlay output ellipse curve (in blue) with estimated parameters: a, b, c, d, e, f :



## Popular Feature Detectors

Popular interest points in images are selected due to invariance to:

- scale, rotation
- illumination variation
- image noise



E.g. Corners

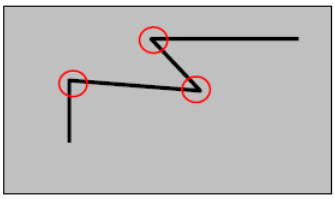
Next: corner detection

Harris Detector (1988)

## Corner Detection: Harris Operator

**Harris corner detector**

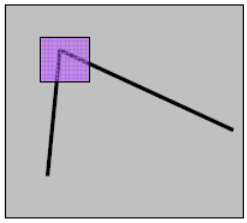
An introductory example:



54/59 C.Harris, M.Stephens. "A Combined Corner and Edge Detector". 1988

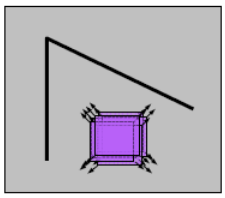
## The Basic Idea

- We should easily recognize the point by looking through a small window
- Shifting a window in *any direction* should give *a large change* in intensity

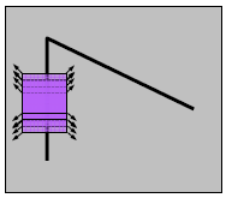


55/59

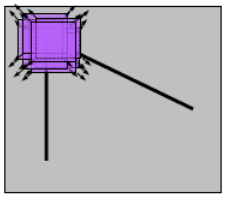
## Harris Detector: Basic Idea



"flat" region:
no change in all directions



"edge":
no change along the edge direction



"corner":
significant change in all directions

56/59

## Corner (Harris) Detector (Mathematics)

Let's analyze the local intensity changes :

Change of intensity for the shift [u,v]:

$$E(u,v) = \sum_{x,y} w(x,y)\left[I(x+u,y+v) - I(x,y)\right]^2$$

Window function | Shifted intensity | Intensity

Window function $w(x,y)$ = 1 in window, 0 outside or Gaussian

57/59

## Corner Detector (Mathematics)

For small shifts (u,v), we have the following approximation (after Taylor series expansion on I(x+u,y+v) and expanding the quadratic term):

$$E(u,v) \cong \begin{bmatrix} u & v \end{bmatrix} G \begin{bmatrix} u \\ v \end{bmatrix}$$

where G is a 2x2 matrix computed from image derivatives in the given window:

$$G = \sum_{x,y} w(x,y) \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix}$$

G is called the Image Structure Tensor

## Image Structure Tensor

$$G(x,y)=\begin{bmatrix} \sum_W (I_x(x_i,y_i))^2 & \sum_W (I_x(x_i,y_i)I_y(x_i,y_i)) \\ \sum_W (I_x(x_i,y_i)I_y(x_i,y_i)) & \sum_W (I_y(x_i,y_i))^2 \end{bmatrix}$$

- W is the window of a fixed size in your image, (xi,yi) pixel coordinates in that window.

- $I_x$ and $I_y$ are the local approximations to the first order partial derivatives of the image J, which is the filtered image I with a Gaussian filter (as we've seen in previous week) :

$$I_x=\frac{\partial I}{\partial x}=\frac{I(x+1,y)-I(x-1,y)}{2} \qquad I_y=\frac{\partial I}{\partial y}=\frac{I(x,y+1)-I(x,y-1)}{2}$$

## Corner Detector (Mathematics)

$$G(x,y)=\begin{bmatrix} \sum_W (I_x(x_i,y_i))^2 & \sum_W (I_x(x_i,y_i)I_y(x_i,y_i)) \\ \sum_W (I_x(x_i,y_i)I_y(x_i,y_i)) & \sum_W (I_y(x_i,y_i))^2 \end{bmatrix}$$

Q: How to analyze the Intensity change in shifting window:

Perform eigenvalue analysis on G

Recall:

$$G=V\Sigma V^{-1} \qquad \lambda_2 \geq \lambda_1 \quad : \text{eigenvalues of G}$$

$\Sigma$ : covariance matrix of the data

$V$ : Eigenvector matrix of G

$$G=V\begin{bmatrix} \lambda_2 & 0 \\ 0 & \lambda_1 \end{bmatrix}V^{-1}$$

## Corner Detector using Structure Tensor

Based on Eigenvalue analysis on G

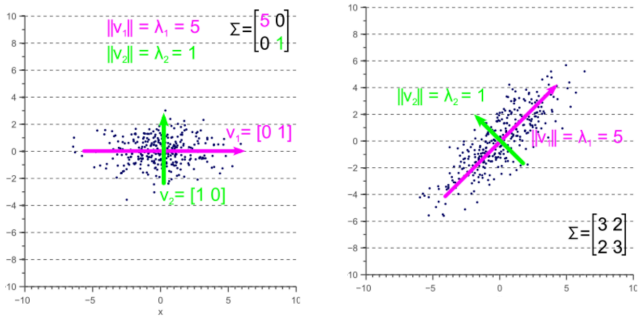
$V$ : Eigenvector matrix of G

$\Sigma$ : covariance matrix of the data

$$G = V \begin{bmatrix} \lambda_2 & 0 \\ 0 & \lambda_1 \end{bmatrix} V^T$$

$\lambda_2 \geq \lambda_1$

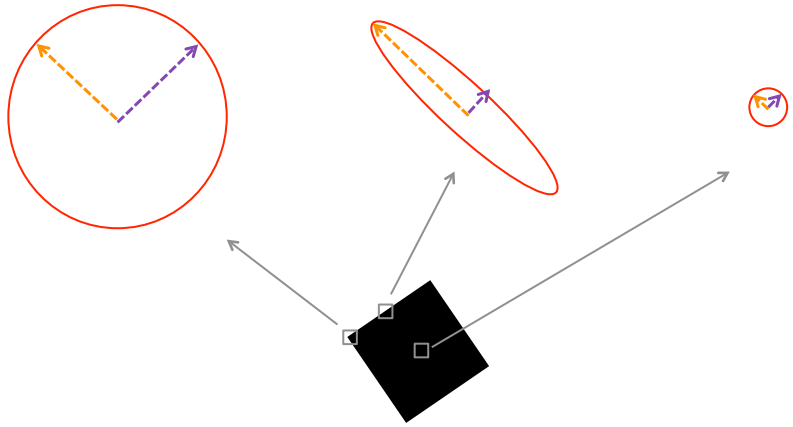
: eigenvalues of G



http://www.visiondummy.com/2014/04/geometric-interpretation-covariance-matrix/

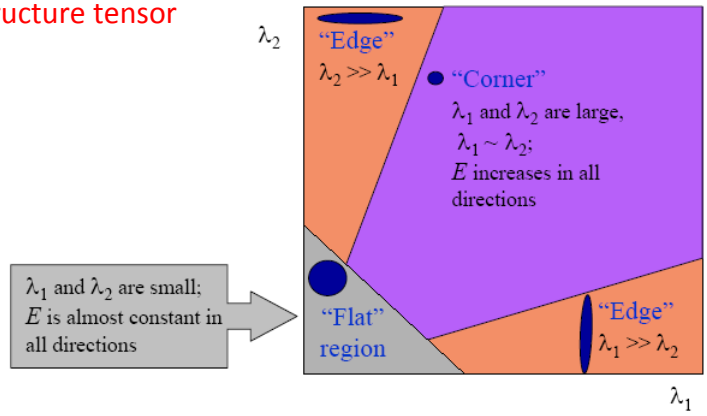
## Eigenvalue analysis

- There are three common scenarios:
  - Both eigenvalues are large: **corner**
  - One eigenvalue is large, the other small: edge
  - Both eigenvalues small: homogeneous region



## Classification of image points using eigenvalues of G

G: image structure tensor



1) If both eigenvalues of G are small, local autocorrelation function (E(u,v)) is FLAT, little change in any direction

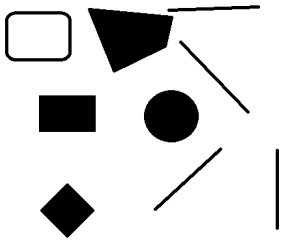
2) If one eigen value is high, the other low, then only there is high shift in one direction → EDGE

3) If both eigen values are high, the local autocorr fn. is sharply peaked → CORNER

# Minimum eigenvalue corner detection

- Since the eigenvalues are positive, one can look at the *smaller* of the two eigenvalues. If this is *large enough*, then a corner has been identified.
- Example: looking at the value of $\lambda_2$ [Shi and Tomasi, '94]

```
% Compute min eigenvalue: see Equation 7 of
% http://www.soest.hawaii.edu/martel/Courses/GG303/Eigenvectors.pdf
lambda2 = 0.5*( (s11+s22)-((s11-s22).^2+4*s12.^2).^0.5 );
figure; imshow(lambda2, []);
```



Image

$\lambda_2$

## Harris Corner Detector defines

A Measure of Corner Response based on evalues of G:

$$R = C(G) = \det(G) - k\ trace^2(G)$$

$$\det(G) = \lambda_1 \lambda_2$$

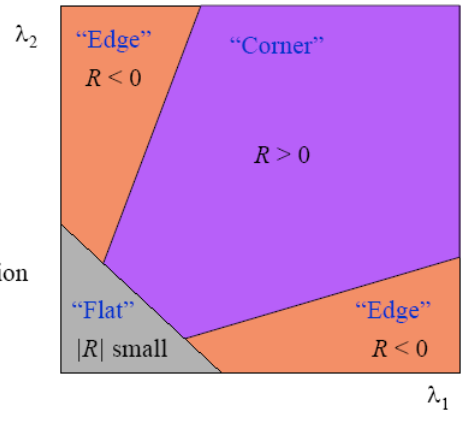
$$trace(G) = \lambda_1 + \lambda_2$$

k – empirical constant, a small value k=0.04 – 0.06

→ Using the 2x2 local structure tensor matrix G, the Harris corner detector THRESHOLDS the quantity R.

## Harris Detector: Mathematics

- $R$ depends only on eigenvalues of G
- $R$ is large for a corner
- $R$ is negative with large magnitude for an edge
- $|R|$ is small for a flat region



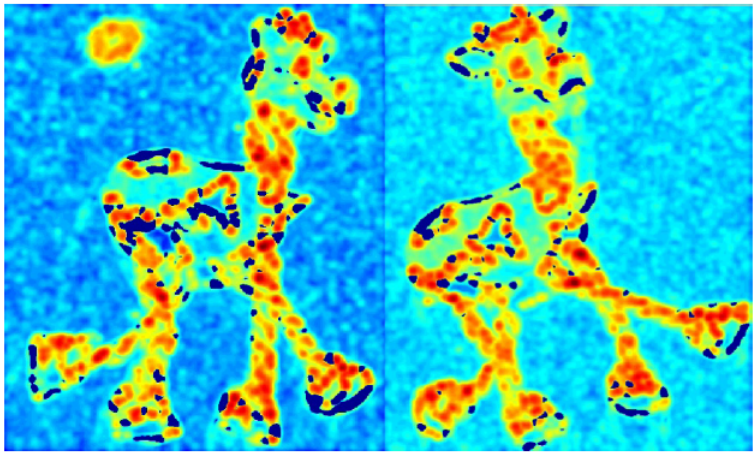
- The Algorithm:
  - *Find points with large corner response function* R (R > *threshold*)
  - *Take the points of local maxima of* R

Harris Detector: Workflow

64/59

Harris Detector: Workflow

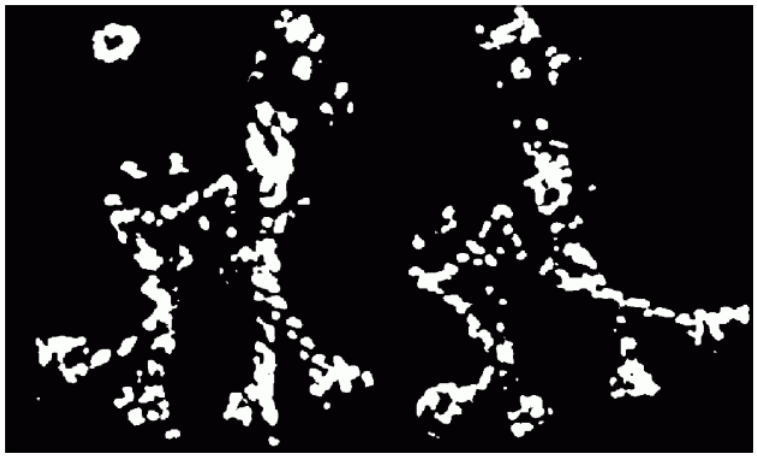
Compute corner response $R$



65/59

Harris Detector: Workflow

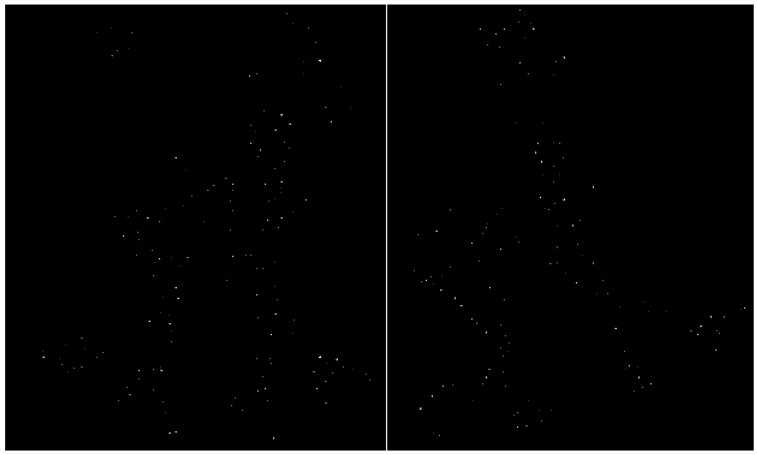
Find points with large corner response: $R$>threshold



66/59

Harris Detector: Workflow

Take only the points of local maxima of $R$

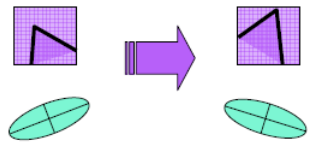


67/59

Harris Detector: Workflow

## Harris Detector: Some Properties

- Rotation invariance

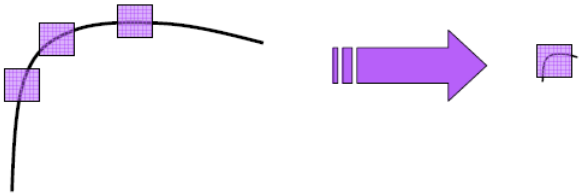


Ellipse rotates but its shape (i.e. eigenvalues) remains the same

*Corner response* $R$ is invariant to image rotation

## Harris Detector: Some Properties

- But: non-invariant to *image scale*!



All points will be classified as edges

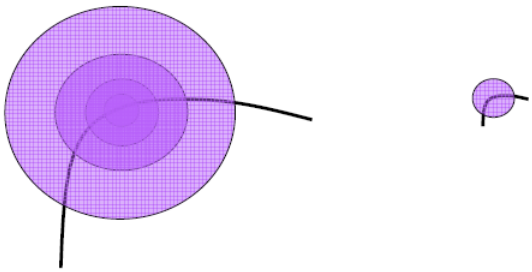
Corner !

70/59

Feature Detection

## Scale Invariant Detection

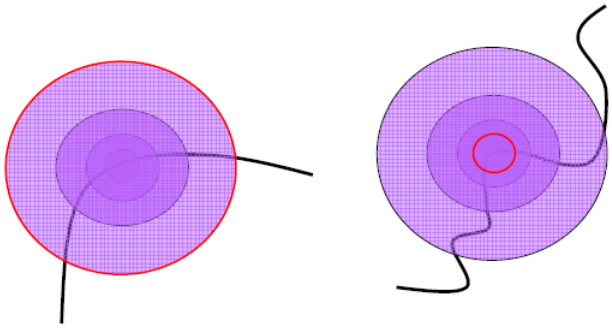
- Consider regions (e.g. circles) of different sizes around a point
- Regions of corresponding sizes will look the same in both images



72/59

## Scale Invariant Detection

- The problem: how do we choose corresponding circles ***independently*** in each image?



73/59

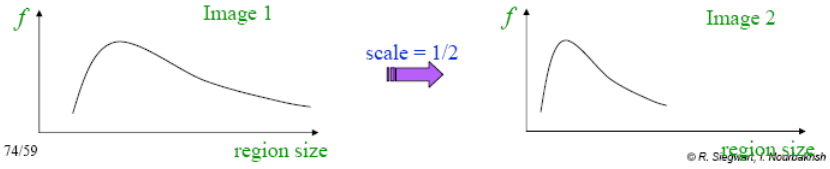
## Scale Invariant Detection

- Solution:
  - *Design a function on the region (circle), which is "scale invariant" (the same for corresponding regions, even if they are at different scales)*

Example: average intensity. For corresponding regions (even of different sizes) it will be the same.

Typically, image gradient based functions are used

  - For a point in one image, we can consider it as a function of region size (circle radius)



74/59

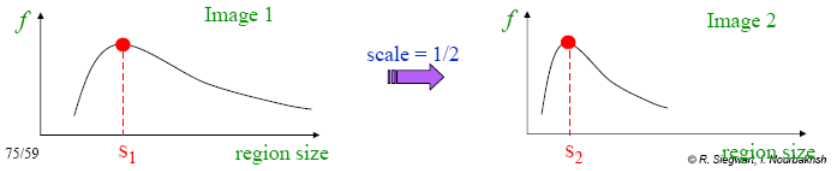
## Scale Invariant Detection

- Common approach:

  Take a local maximum of this function

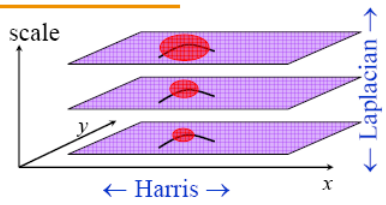
  Observation: region size, for which the maximum is achieved, should be *invariant* to image scale.

Important: this scale invariant region size is found in each image independently!

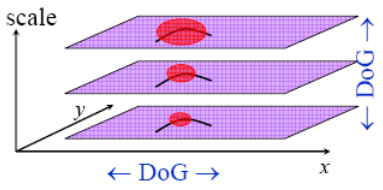


## Scale Invariant Detectors

- Harris-Laplacian[1]
  *Find local maximum of:*
  - *Harris corner detector in space (image coordinates)*
  - *Laplacian in scale*



- SIFT (Lowe)[2]
  *Find local maximum of:*
  - Difference of Gaussians in space and scale



[1] K.Mikolajczyk, C.Schmid. "Indexing Based on Scale Invariant Interest Points". ICCV 2001

78/59

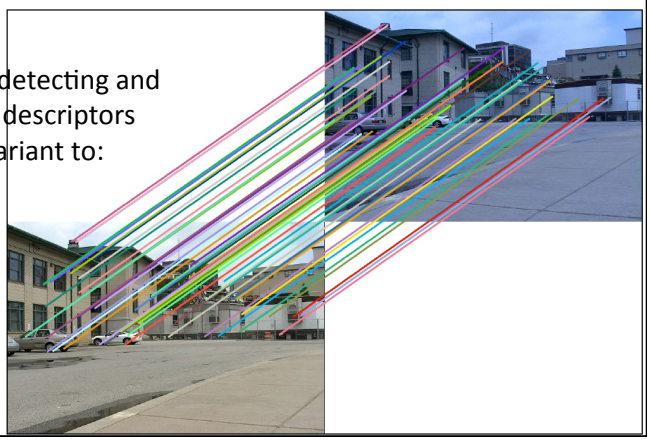
© R. Siegwart, I. Nourbakhsh

## Feature Matching Problem

- After you detect features in 2 images, how to match them?
- You have to define a descriptor for a feature: The simplest solution is the intensities of its spatial neighbors. This might not be robust to brightness change or small shift/rotation.
- Therefore, typically, features are based on gradients of images

e.g. SIFT detector:
SIFT is an approach for detecting and extracting local feature descriptors that are reasonably invariant to:

- Rotation
- Scaling
- Small changes in viewpoint
- illumination



END OF LECTURE on Feature Extraction

Recall Learning objectives of Week 8: Students are able to:

3. Define and construct segmentation, feature extraction, and visual motion estimation algorithms to extract relevant information from images

## Next assignment: Work on feature extraction and template matching

Reading Assignments:

[Klette Book] 1.1, 1.3, 2.1.1, 2.1.2

[Gonzalez and Woods]: Chap 3.1 – 3.3

Those interested: Advanced Feature Extractors like SIFT: David Lowe, Distinctive Image Features from Scale-Invariant Key Points, International Journal of Computer Vision 2004.

Extra Slides

## Scale Invariant Detection

- A "good" function for scale detection: has one stable sharp peak

- For usual images: a good function would be a one which responds to contrast (sharp local intensity change)

76/59

## Scale Invariant Detection

- Functions for determining scale

$$f = \text{Kernel} * \text{Image}$$

Kernels:

$$L = \sigma^2 \left( G_{xx}(x, y, \sigma) + G_{yy}(x, y, \sigma) \right)$$

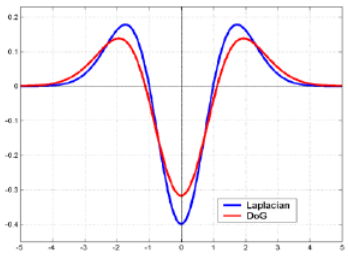
(Laplacian)

$$DoG = G(x, y, k\sigma) - G(x, y, \sigma)$$

(Difference of Gaussians)

where Gaussian

$$G(x, y, \sigma) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{x^2+y^2}{2\sigma^2}}$$



Note: both kernels are invariant to *scale* and *rotation*

77/59

EXTRA MATERIAL

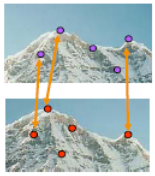
## Harris Detector: Some Properties

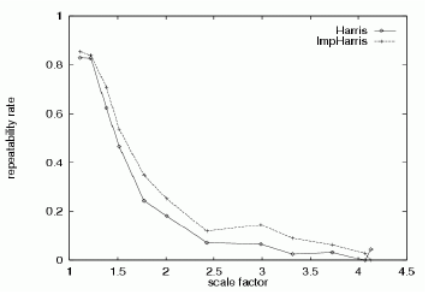
- Quality of Harris detector for different scale changes

# points repeated btw two images wrt total # detected points in each image (min of the two)

Repeatability rate:

$$\frac{\text{\# correspondences}}{\text{\# possible correspondences}}$$





71/59 C.Schmid et.al. "Evaluation of Interest Point Detectors". IJCV 2000

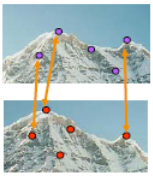
Interest points which can not be observed in both images corrupt the repeatability measure, therefore only points which lie in the common scene part used to compute repeatability

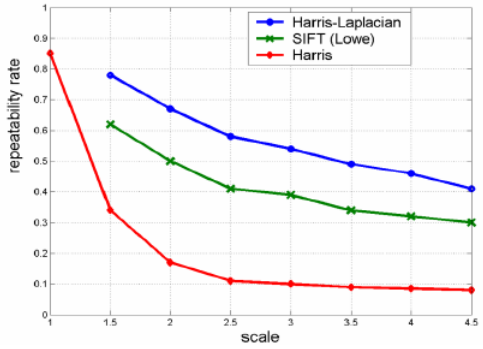
## Scale Invariant Detectors

- Experimental evaluation of detectors w.r.t. scale change

Repeatability rate:

$$\frac{\text{\# correspondences}}{\text{\# possible correspondences}}$$





79/59 K.Mikolajczyk, C.Schmid. "Indexing Based on Scale Invariant Interest Points". ICCV 2001

# points repeated btw two images wrt total # detected points in each image (min of the two)

Interest points which can not be observed in both images corrupt the repeatability measure, therefore only points which lie in the common scene part used to compute repeatability

# SIFT
# (Scale Invariant Feature Transform)

77

## SIFT stages:

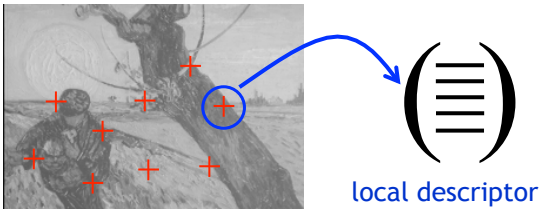
- Scale-space extrema detection
- Keypoint localization

detector

- Orientation assignment
- Keypoint descriptor generation

descriptor

matching



A 500x500 image gives about 2000 features

78

## We want invariance!!!

- Good features should be robust to all sorts of nastiness that can occur between images.

79

## Types of invariance

- Illumination

80

## Types of invariance

- Illumination
- Scale

81

## Types of invariance

- Illumination
- Scale
- Rotation

82

## Types of invariance

- Illumination
- Scale
- Rotation
- Affine

83

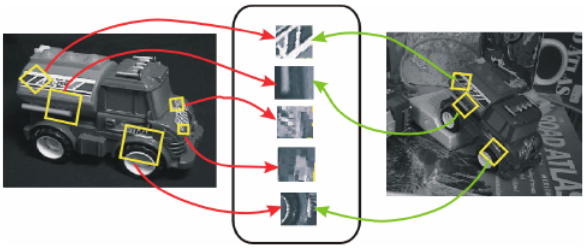
## Types of invariance

- Illumination
- Scale
- Rotation
- Affine
- Full Perspective

84

## Invariant Local Features

- Image content is transformed into local feature coordinates that are invariant to translation, rotation, scale, and other imaging parameters



81/59

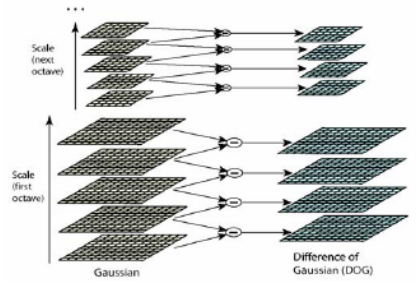
## Detection stages for SIFT features

- Scale-space extrema detection
- Keypoint localization
- Orientation assignment
- Generation of keypoint descriptors.

82/59

## Scale-space extrema detection

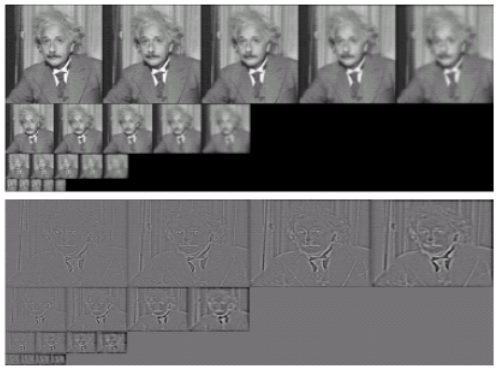
- The first step toward the detection of interest points is the convolution of the image with Gaussian filters at different scales, and the generation of Difference-of-Gaussian images (DoG) from the difference of adjacent blurred images



83/59

## Scale-space extrema detection

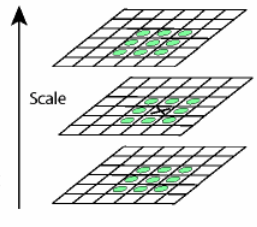
- Gaussian blurred images grouped by octave
- Difference of Gaussian images (DoG) grouped by octave



84/59

## Scale-space extrema detection

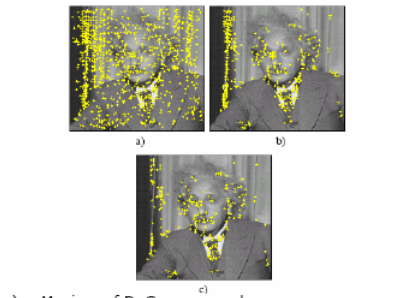
- SIFT keypoints are identified as local maxima or minima of the DoG images across scales.
- Each pixel in the DoG images is compared to its 8 neighbors at the same scale, plus the 9 corresponding neighbors at neighboring scales.
- If the pixel is a local maximum or minimum, candidate keypoint.



85/59

## Key point localization

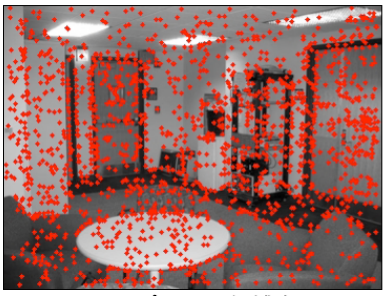
- For each candidate keypoint:
  - *Interpolation of nearby data is used to accurately determine its position.*
  - *Keypoints with low contrast are removed (b).*
  - *Responses along edges are eliminated (c).*

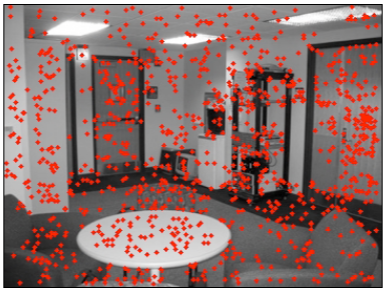


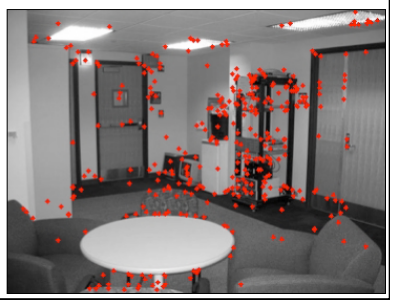
a) Maxima of DoG across scales
b) Remaining keypoints after removal of low contrast points
c) Remaining keypoints after removal of edge responses

86/59

## Remove low contrast and edges



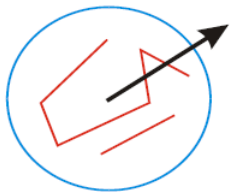


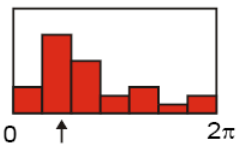


91

## Orientation assignment

- To determine the keypoint orientation, a gradient orientation histogram is computed in the neighborhood of the keypoint.
- Peaks in the histogram correspond to dominant orientations. If more than one peak is found, a separated feature is assigned to the same point location.
- All the properties of the keypoint are measured relative to the keypoint orientation, this provides invariance to rotation.

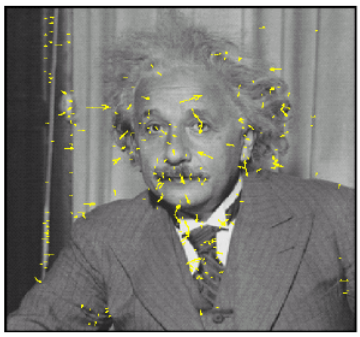




87/59

## Key point localization

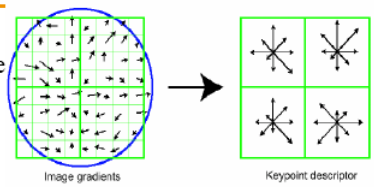
- Final keypoints with selected orientation and scale



88/59

## Generation of keypoint descriptor

- A keypoint descriptor is created by first computing the gradient magnitude and orientation at each image sample point in a region around the keypoint location, as shown on the left.



- These samples are then accumulated into orientation histograms summarizing the contents over 4x4 sub regions, as shown on the right, with the length of each arrow corresponding to the sum of the gradient magnitudes near that direction within the region.
- The descriptor is formed from a vector containing the values of all the orientations histogram entries, corresponding to the arrows of the right side.
- This vector is then normalized to enhance invariance to changes in illumination.

89/59

## Advantages of SIFT features

- Locality: features are local, so robust to occlusion and clutter (no prior segmentation)
- Distinctiveness: individual features can be matched to a large database of objects
- Quantity: many features can be generated for even small objects
- Efficiency: close to real-time performance

90/59

## SIFT output: Feature Matching example

96

# SIFT Detector Application Examples

## Place recognition

97/59

# SIFT Detector Application Examples

## Planar recognition

- Planar surfaces can be reliably recognized at a rotation of 60° away from the camera
- Affine fit approximates perspective projection
- Only 3 points are needed for recognition

94/59

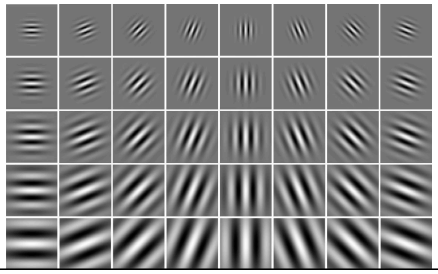
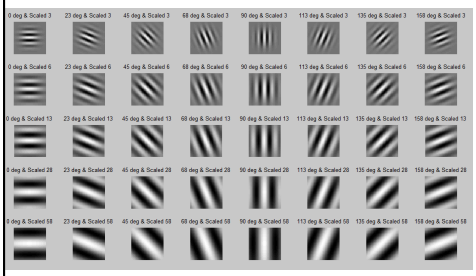
## Gabor Filters

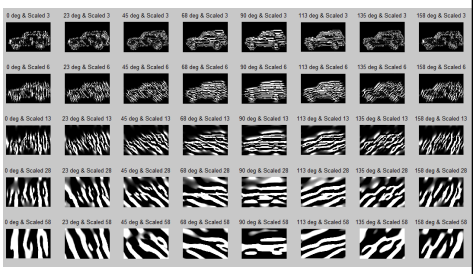
- Gabor Filter is a filter used for edge detection. Frequency and orientation representations of Gabor filters are similar to those of the human visual system, and they have been found to be particularly appropriate for texture representation and discrimination.
- In the spatial domain, a 2D Gabor filter is a Gaussian kernel function modulated by a sinusoidal plane wave.

$$G(x, y) = \exp\left(-\frac{(X^2 + \gamma^2 Y^2)}{2\sigma^2}\right)\cos\left(\frac{2\pi}{\lambda}X\right)$$



# Gabor Filters

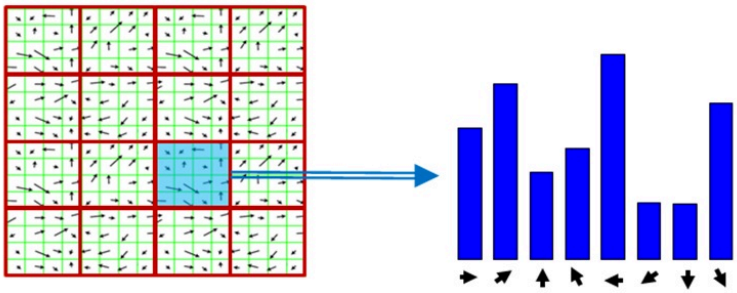




http://www.mathworks.com/matlabcentral/fileexchange/44630-gabor-feature-extraction

# Histogram of Oriented Gradients (HOG)

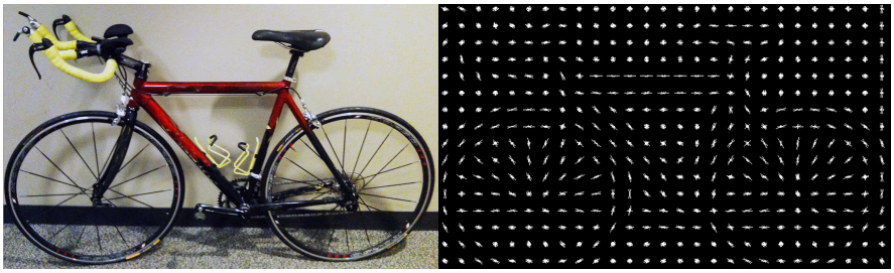
- The histogram of oriented gradients (HOG) is a feature descriptor used in computer vision and image processing for the purpose of object detection.
- The technique counts occurrences of gradient orientation in localized portions of an image. This method is similar to that of scale-invariant feature transform descriptors (SIFT) and Speeded Up Robust Features (SURF) but differs in that it is computed on a dense grid of uniformly spaced cells and uses overlapping local contrast normalization for improved accuracy.



https://www.youtube.com/watch?v=0Zib1YEE4LU&feature=plcp

# HOG Features

The HOG features are often used to detect objects such as people and cars. They are useful for capturing the overall shape of an object. For example, in the following visualization of the HOG features, you can see the outline of the bicycle.

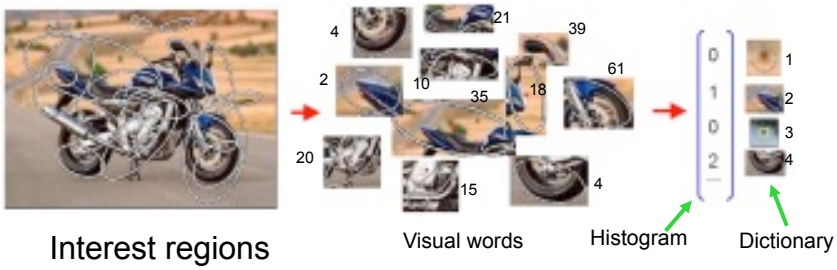


Matlab's trainCascadeObjectDetector

# Blob Detection

- Blob detection methods are aimed at detecting regions in a digital image that differ in properties, such as brightness or colour, compared to surrounding regions. Informally, a blob is a region of an image in which some properties are constant or approximately constant; all the points in a blob can be considered in some sense to be similar to each other.
- Given some property of interest expressed as a function of position on the image, there are two main classes of blob detectors:
  - (i) differential methods, which are based on derivatives of the function with respect to position (such as The Laplacian of Gaussian), and
  - (ii) methods based on local extrema, which are based on finding the local maxima and minima of the function. With the more recent terminology used in the field, these detectors can also be referred to as interest point operators, or alternatively interest region operators

# Bag of features (words)



Stack visual word histograms as columns in matrix

Throw away spatial information!

Note that for the bag of features approach to be effective, majority of each image's area must be occupied by the subject of the category, for example, an object or a type of scene.
